# Ecology and ecosystem

TIIAME

# Introduction to Ecology

- The meaning of the word ecology was given by German Biologist Hackle in 1869.
- The word ecology is derived from Greek words 'Oikos' meaning house, habitat or place of living and 'Logos' meaning to study.
- Ecology is defined as the study of interrelationship of different organisms with each other and with their environment. It is concerned with the general principles that apply to both animals and plants.

### Objectives of Ecological Studies

- It is important for humanity to understand its environment because we have the ability to modify the environment through the use of technology, and through overexploitation of natural resources as a result of greed or sheer pressure of numbers. Therefore, ecology is more than just the understanding of the interrelationships between organisms and their environment; it also has social, political, economic and technological dimensions.
- It also is a study of evolutionary development of organisms, the biological productivity and energy flow in the natural system.
- To develop mathematical models to relate interaction of parameters and to predict the effects

# Classification of Ecology

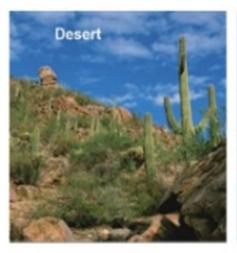

#### Based on study area :

- Autecology: It deals with the study of an individual species
  of organisms and it's population. The ecologists study the
  behavior and adaptations of particular species to the
  environmental condition at every stage of that individual's
  life cycle. It is also called the Species ecology.
- Synecology: It deals with the study of communities, their composition, their behavior and relation with the environment. It is also called as Ecology of communities. It is further divided into 3 types: 1) Population Ecology
  - 2) Community Ecology
  - 3) Ecosystem Ecology

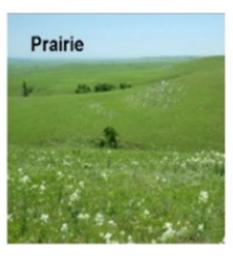

# Ecosystem

- The term Ecosystem was first proposed by A.G. Tansley in 1935. he defined it as "the system resulting from the interaction of all the living and non living factors of the Environment.
- An ecosystem consists of the biological community that occurs in some locale, and the physical and chemical factors that make up its non-living or abiotic environment. There are many examples of ecosystems

   a pond, a forest, an estuary, a grassland.

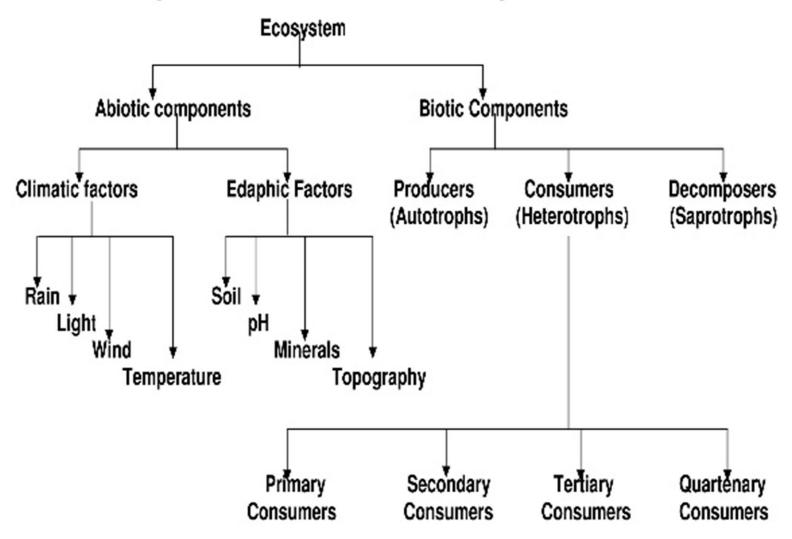

Various types of Ecosystem

# Types of Ecosystem

2. Artificial (Man Engineered) **Ecosystems**: These are maintained artificially by man where by addition of energy and planned manipulation, natural balance is disturbed regularly e.g., crop land ecosystem.

Crop land ecosystem

#### Abiotic

- Consists of Non-living chemical & physical components such as water, air, nutrients in the soil or water & Solar Energy.
- Physical & chemical factors that influence living organisms in land (terrestrial) ecosystem & aquatic life zones.
- Abiotic factors can act as LIMITING FACTORS that keep a population at a certain level.

Abiotic Components are mainly of two types:

Climatic Factors:

which include rain, temperature, light, wind, etc.

2) Edaphic Factors:

which include soil, pH, Topography, Minerals, etc.

#### 2. Biotic factors

- All the living things that directly or indirectly affect the ecosystem biotic factors interact with other living organisms and the physical environment can also be *Limiting Factors* ex. disease (bacteria), predators, food resources.
- Made up of biological components consisting of living and dead plants, animals and microorganisms.
- •The Major Biological Components of Ecosystem:

#### a. Producers (Autotrophs)(self-feeders)

- Make their own food from compounds that are obtained from their environment.
- Are the source of all food in an ecosystem.
- On land most producers are green plants.
- In freshwater and marine ecosystems, algae and plants are the major producers near shorelines.
- In open water, the dominant producers are *phytoplankton* (most of them microscopic) that float or drift in the water.
- Most producers capture sunlight to make carbohydrates (such as glucose) by photosynthesis.

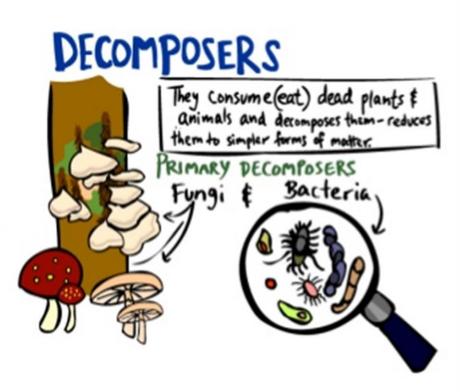

**b.** Consumers (Heterotrophs) ("other feeders")

Get their energy and nutrients by feeding on other organisms or their remains.

- Primary consumers: Are those that eat producers (plants) as a source of food. They are also known as herbivores.
- Secondary consumers or carnivores: Eat other animals.
- iii. Tertiary Consumers: Large Carnivores which feed on secondary consumers.
- iv. Quaternary Consumers: Largest Carnivores that feed on tertiary consumers. They are not eaten by any animals.
- Omnivores: Have mixed diet that include both plants and animals.

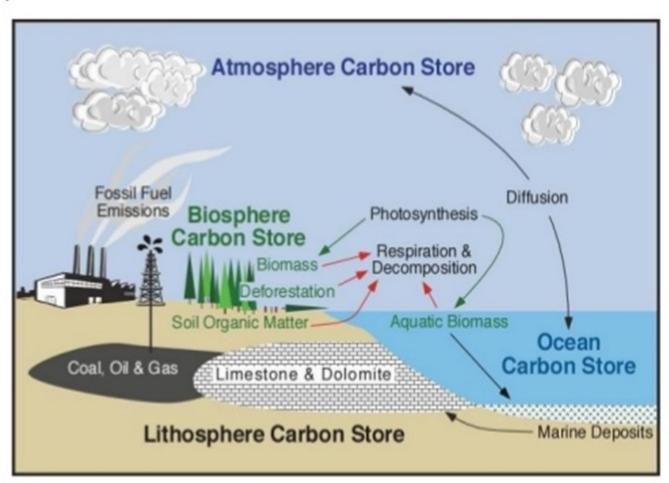

#### Decomposer:

- Mostly certain types of bacteria and fungi are specialized consumers that recycle organic matter in ecosystems.
- They do this by breaking down (biodegrading) dead organic material to get nutrients and releasing the resulting simpler inorganic compounds into the soil and water, where they can be taken up as nutrients by producers.

#### Carbon Cycle

 The carbon cycle is the biogeochemical cycle by which carbon is exchanged among the biosphere, pedosphere, geosphere, hydrosphere, and atmosphere of the Earth.

### Forest Ecosystem

 They have a predominance of trees that are interspersed with large number of species of herbs, shrubs, climbers, lichens algae & a variety of wild animals & birds.

Depending upon the climatic conditions forests can be of different

types:

1. Tropical Rain Forest

- 2. Tropical Deciduous forests
- 3. Tropical Scrub Forests
- 4. Temperate Rain Forests
- 5. Temperate Deciduous Forests
- 6. Evergreen Coniferous Forests

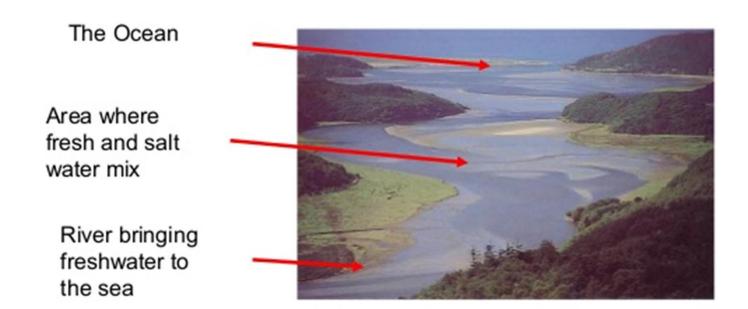

#### Grass Land Ecosystem

- A grassland ecosystem is an ecological unit that has physical factors like water, soil and air, which help to establish that animals live there. The plants, animals, microbes along with the water, soil and air they live in help to create the ecosystem.
- About 1.2 × 10<sup>8</sup> mi<sup>2</sup> (4.6 × 10<sup>7</sup> km<sup>2</sup>) of the Earth's surface is covered with grasslands, which make up about 32% of the plant cover of the world.
- Grasslands occur in regions that are too dry for forests but that have sufficient soil
  water to support a closed herbaceous plant canopy that is lacking in deserts.
- Different kinds of grasslands develop within continents, and their classification is based on similarity of dominant vegetation, presence or absence of specific dominant species, or prevailing climate conditions.
- Temperate grasslands
- Tropical grasslands
- Polar grasslands
- Grassland Soils are highly fertile & contain large amount of exchangeable bases & organic matter.

#### **Estuaries**

- An estuary is a semi closed coastal body of water that has free connection with sea.
- An area in which fresh water from a river mixes with salt water from the ocean; a transition area from the land to the ocean. Other names: bay, sound, lagoon, harbor, or bayou

#### Characteristics of Estuaries

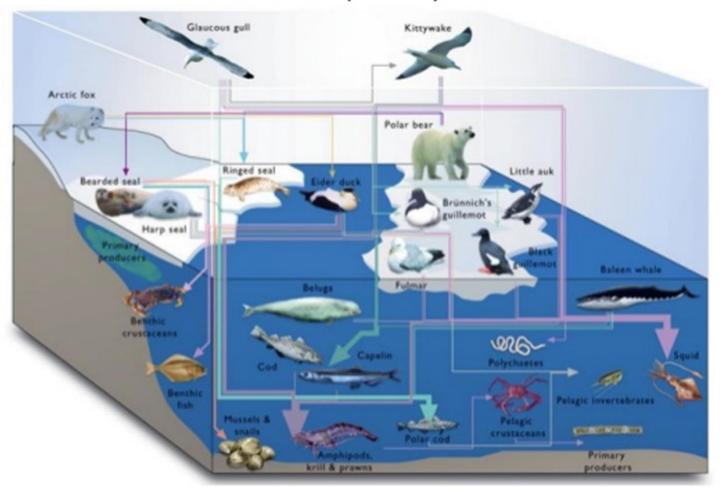

- Very nutrient rich ecosystems → leads to high productivity and high biodiversity.
- There is a gradual increase in salinity as you go from the river (0-5ppt) to the middle of the estuary (5-25ppt), to the ocean (>25 ppt).
  - ppt = parts per thousand
- Sediment settles out in the estuary when the water slows down.
- Nutrients accumulates on the bottom (benthic zone).
- Pollutants are absorbed in estuaries.

#### Aquatic Ecosystem

- An aquatic ecosystem is an ecosystem in a body of water. Communities of organisms that are dependent on each other and on their environment live in aquatic ecosystems
- Aquatic Ecosystem can be further classified into:
  - 1. Fresh water Ecosystem
    - Pond Ecosystem: small bodies of freshwater with shallow and still water, marsh, and aquatic plants
    - Lake Ecosystem: slow moving water like pools, ponds, and lakes.
    - River Ecosystem : large streams flowing downwards from the mountain highlands into the sea
  - Marine Ecosystem: cover approximately 71% of the Earth's surface and contain approximately 97% of the planet's water
