1. Introduction

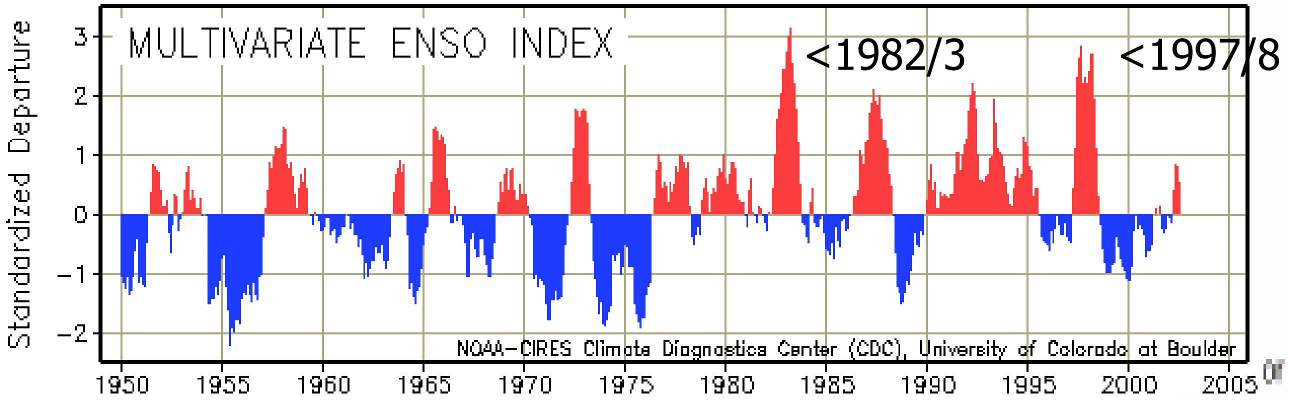
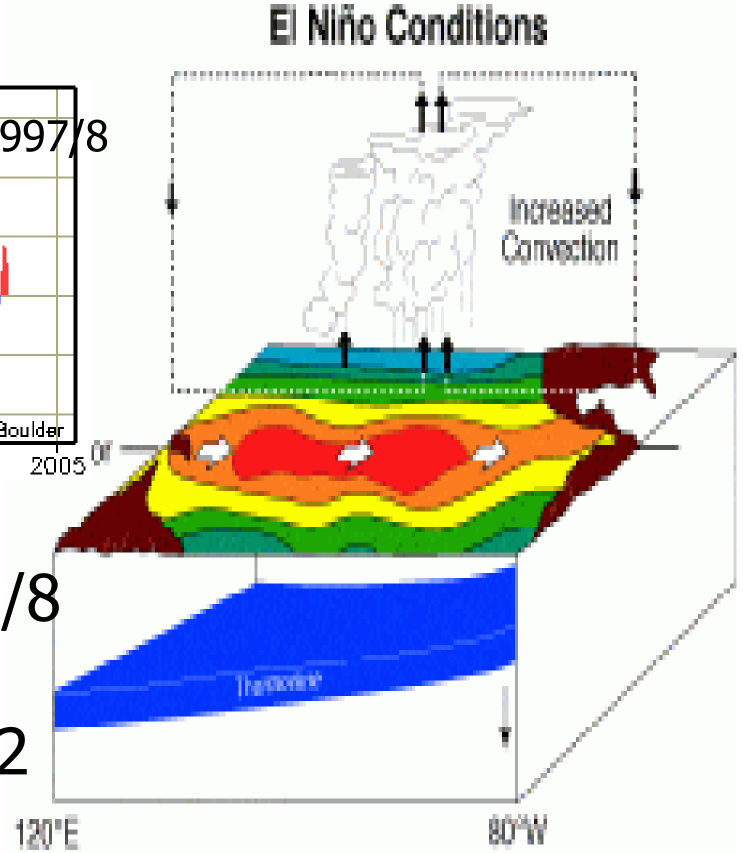
Motivation

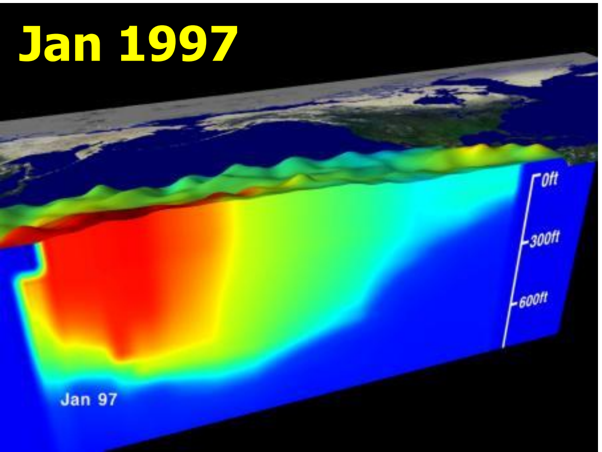
- Empirical versus dynamical forecasts?
- Why not combine both types of forecast in order to use ALL possible information?
- Ensemble forecasts + probability model → probability forecasts
- Use sample of ensemble forecasts to update historical (prior) probability information (post-forecast assimilation)

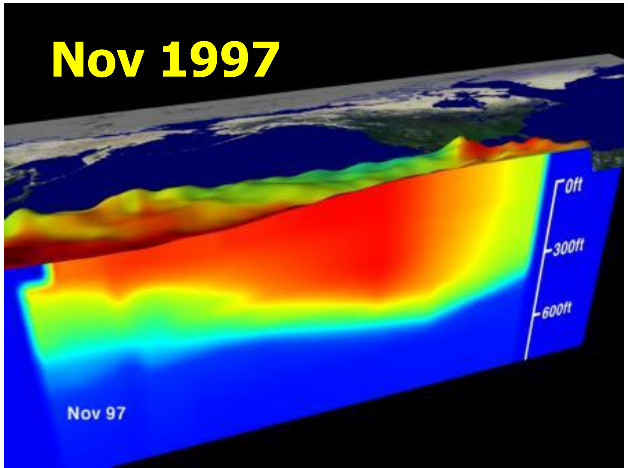
El Nino – Southern Oscillation

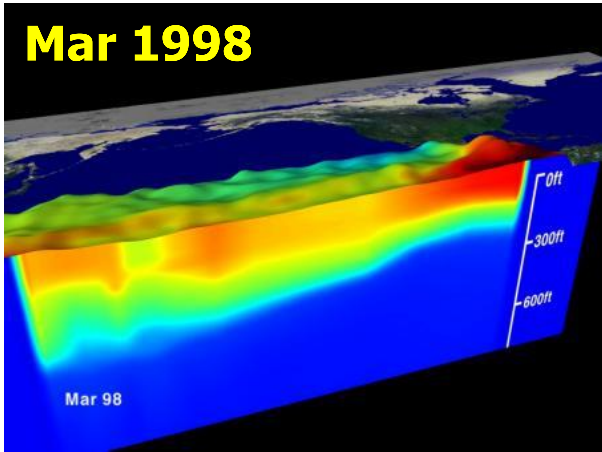




- Big El Nino events in 1982/3 and 1997/8
- La Nina/normal conditions since 1998
- El Nino event predicted for end of 2002







Recent sea temperature anomalies 16 Sep 2002

NOAA 50KM GLOBAL ANALYSIS: SST – Climatology (C), 9/16/2002

←ENSO forecasts from ECMWF, Reading
Sep 2002-Feb 2003

DATA

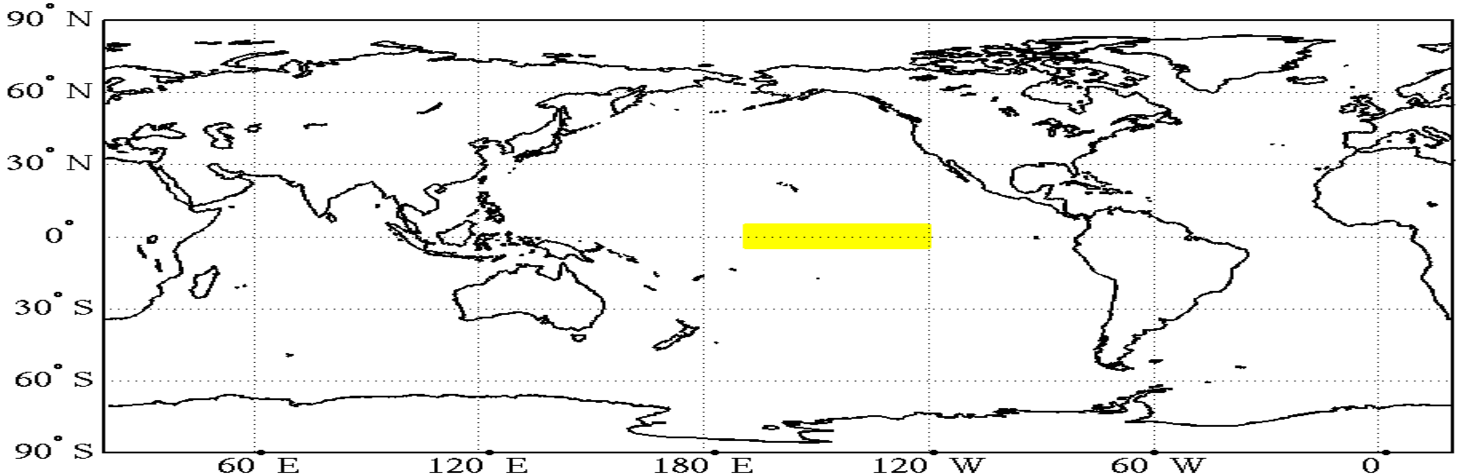
Sea Surface Temperatures (SST)

"at" location Nino 3.4

(5S - 5N , 170W - 120W)

December means of Nino 3.4:

- Reynolds SST : 1950-2001
- ECMWF DEMETER ensemble forecasts: 1987-1999



Some notation …

- Observed Dec Nino-3.4 θ_t
- Ensemble mean forecast $\overline{X}_t$
- Ensemble standard deviation s_X
- Normal (Gaussian) probability forecasts:

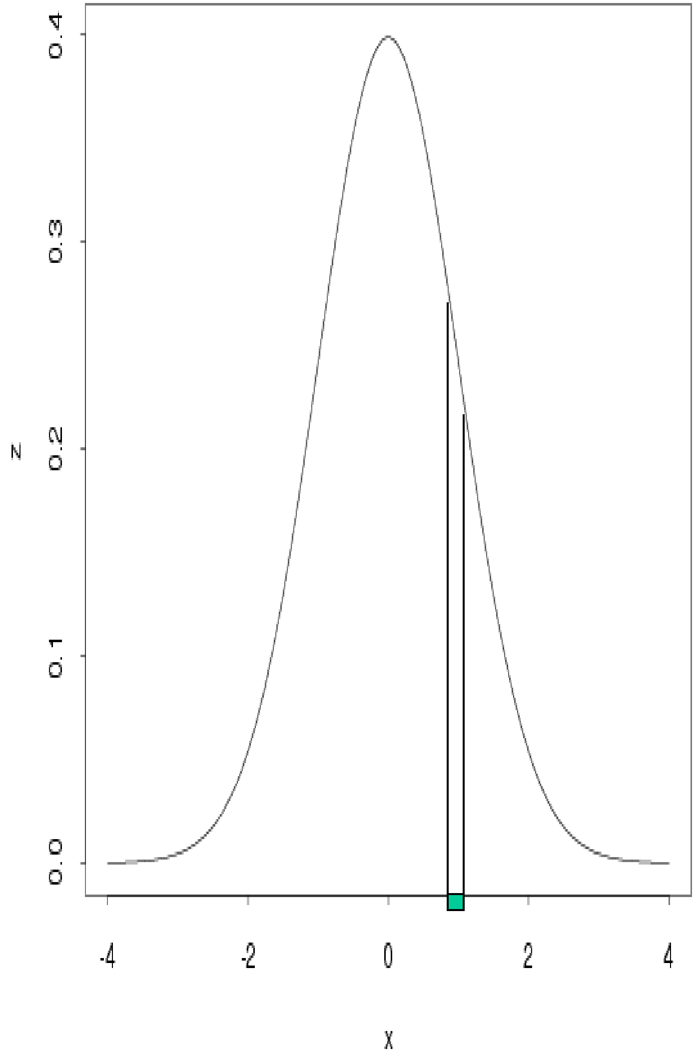
$$\hat{\theta}_t \sim N(\hat{\mu}_t, \hat{\sigma}_t)$$

$$\hat{\mu}_t = \text{forecast mean value}$$

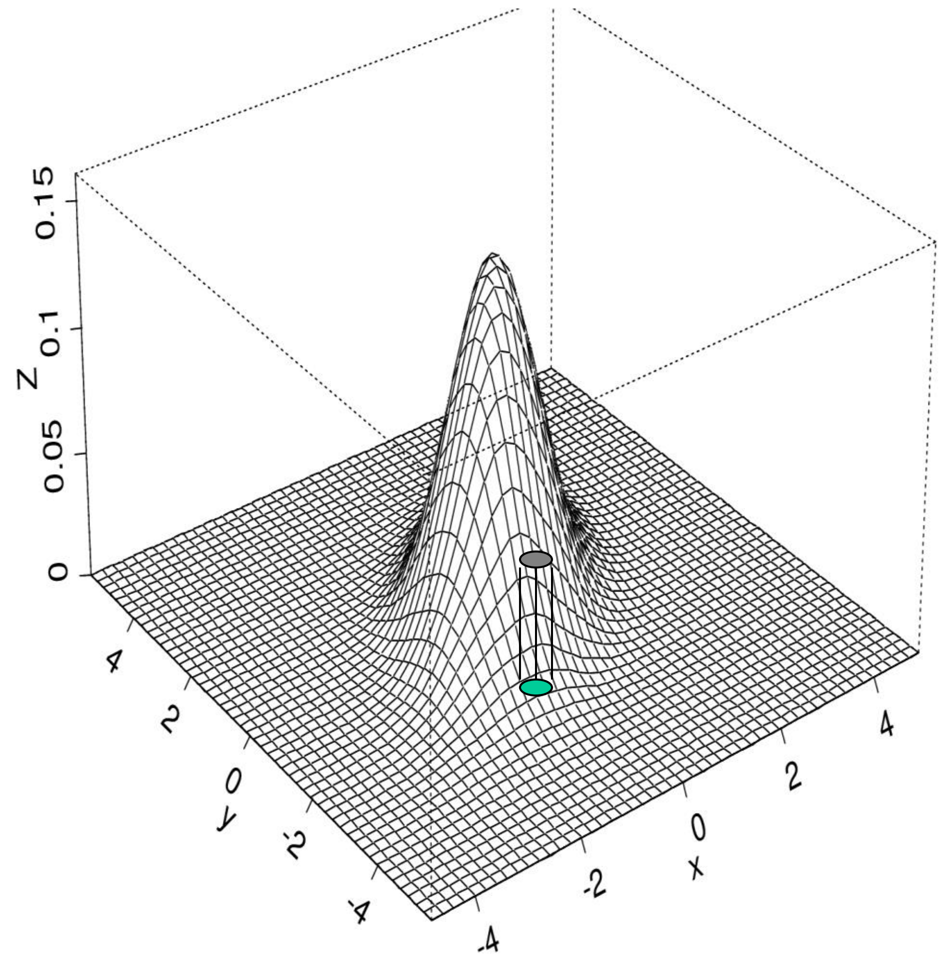
$$\hat{\sigma}_t = \text{forecast uncertainty}$$

2. Conditioning and Bayes theorem

Probability density functions (distributions)



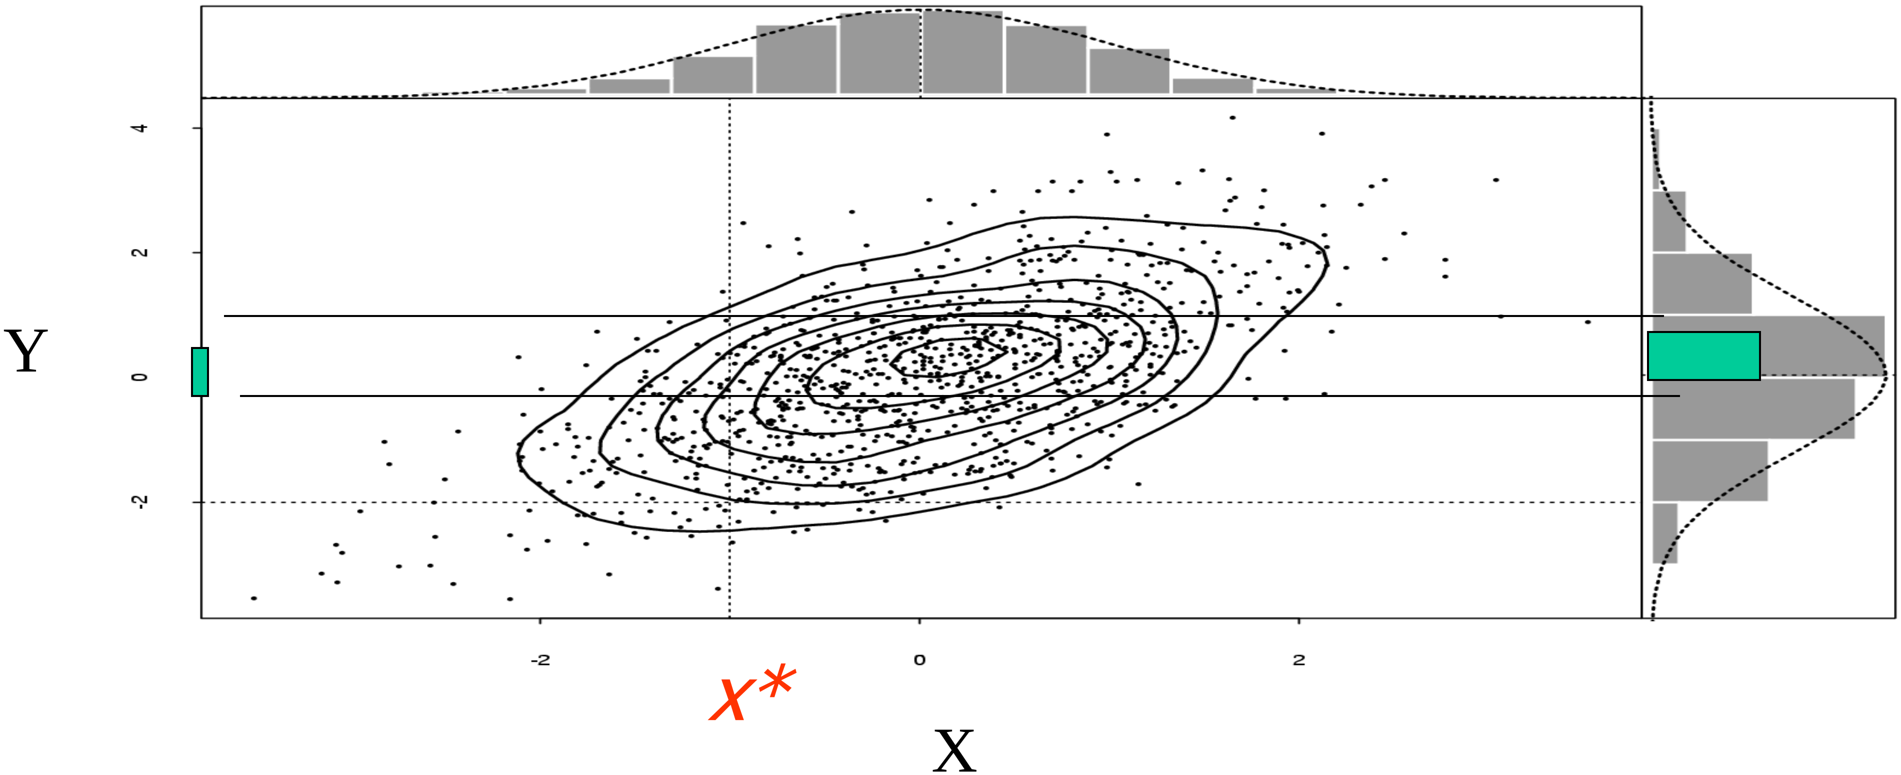
Uni-dimensional



Bi-dimensional
or Joint
distribution of X & Y

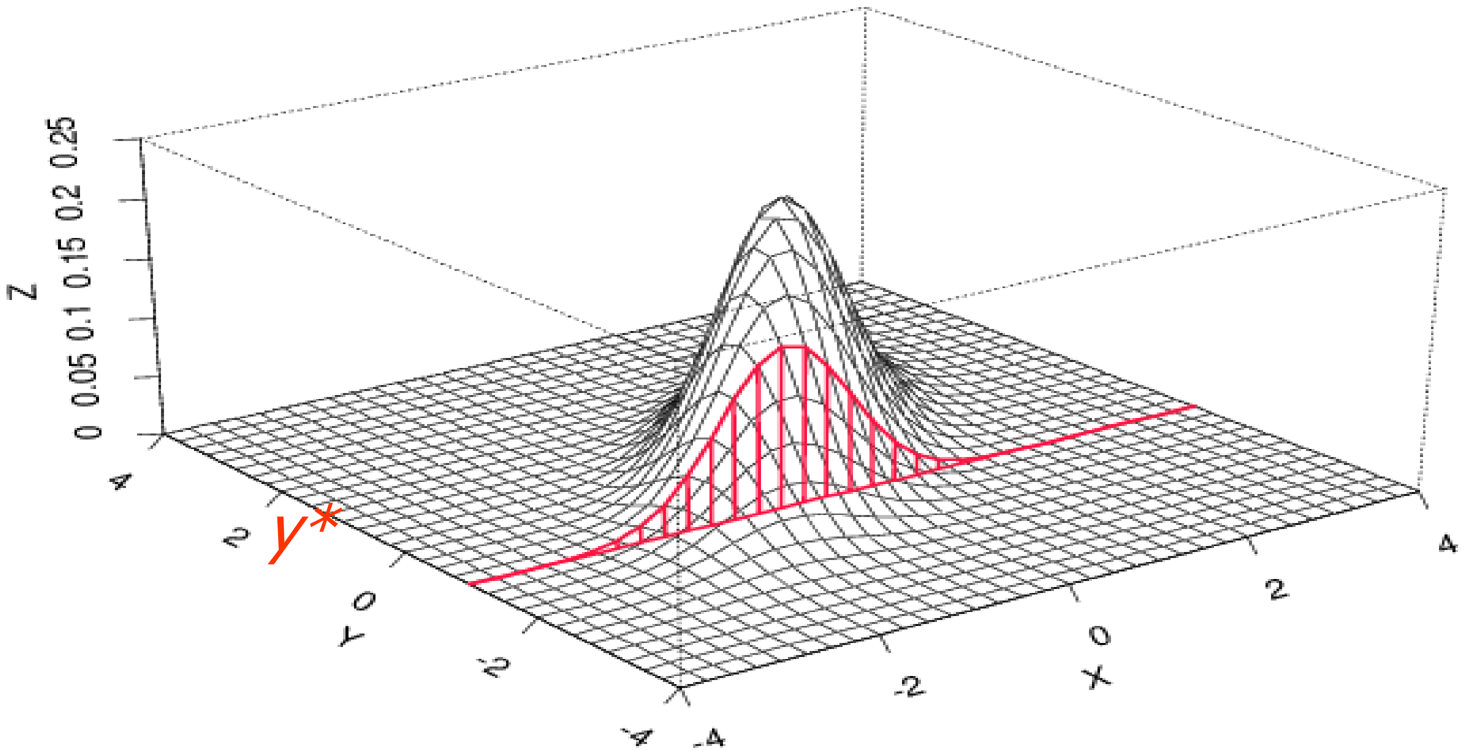
Marginal distributions

$$p(x^*) = \int p(x^*, y)\, dy$$



Conditional distributions

$$p(x \mid y^*) = p(x, y^*) / p(y^*)$$



Conditional-chain Rule

$$p(y)\,p(x|y) = p(x, y) = p(x)\,p(y|x)$$

Bayes Theorem

$$p(x|y) = p(x, y) / p(y)$$

$$\propto p(x, y)$$

$$= p(x)\,p(y|x)$$

Thomas Bayes
1701-1761

An Essay towards Solving a Problem
In the Doctrine of Chances.
Philosophical Transactions
of the Royal Society, 1763

The process of belief revision on any event
W (the weather)
consists in updating the probability of W when new information
F (the forecast)
becomes available

$$\mathbf{p(W \mid F) \propto p(W)\ p(F \mid W)}$$

$$\mathbf{p(W) = N(\mu, \sigma^2)}$$

$$\mathbf{p(F \mid W) = N(\alpha + \beta W, \gamma V)}$$

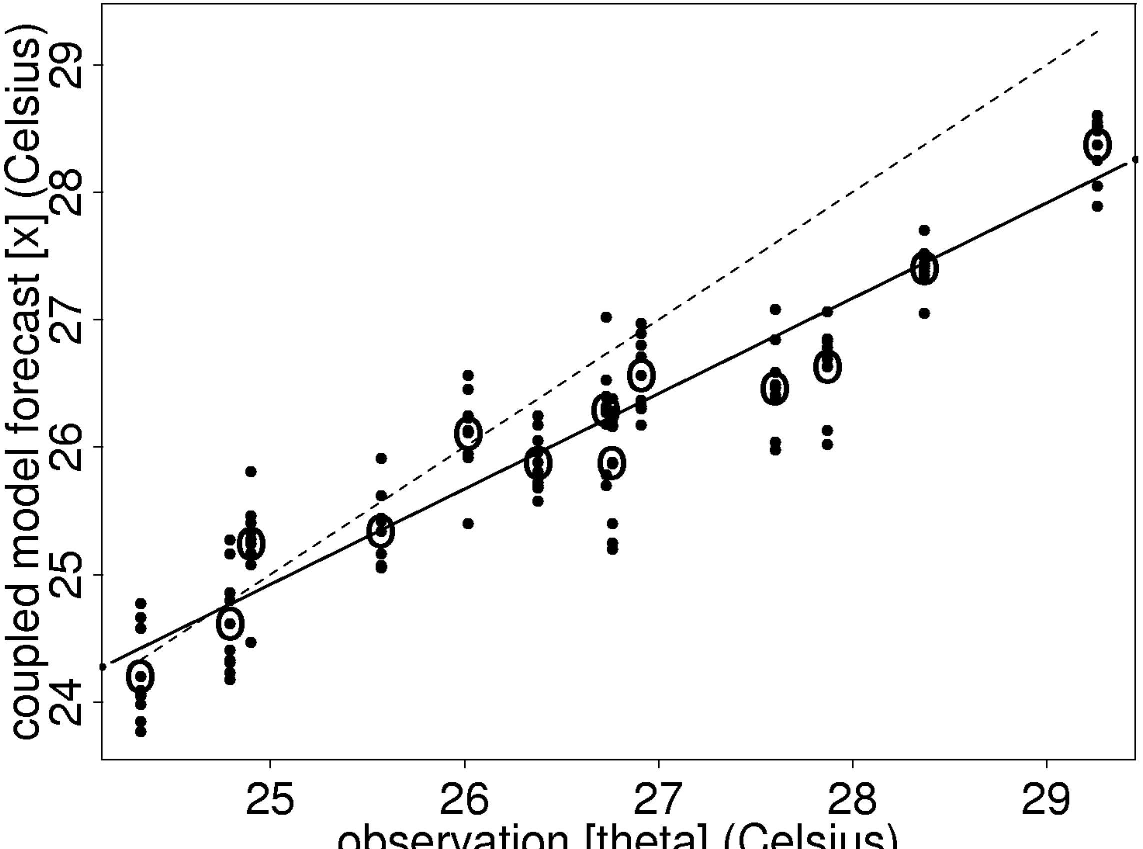
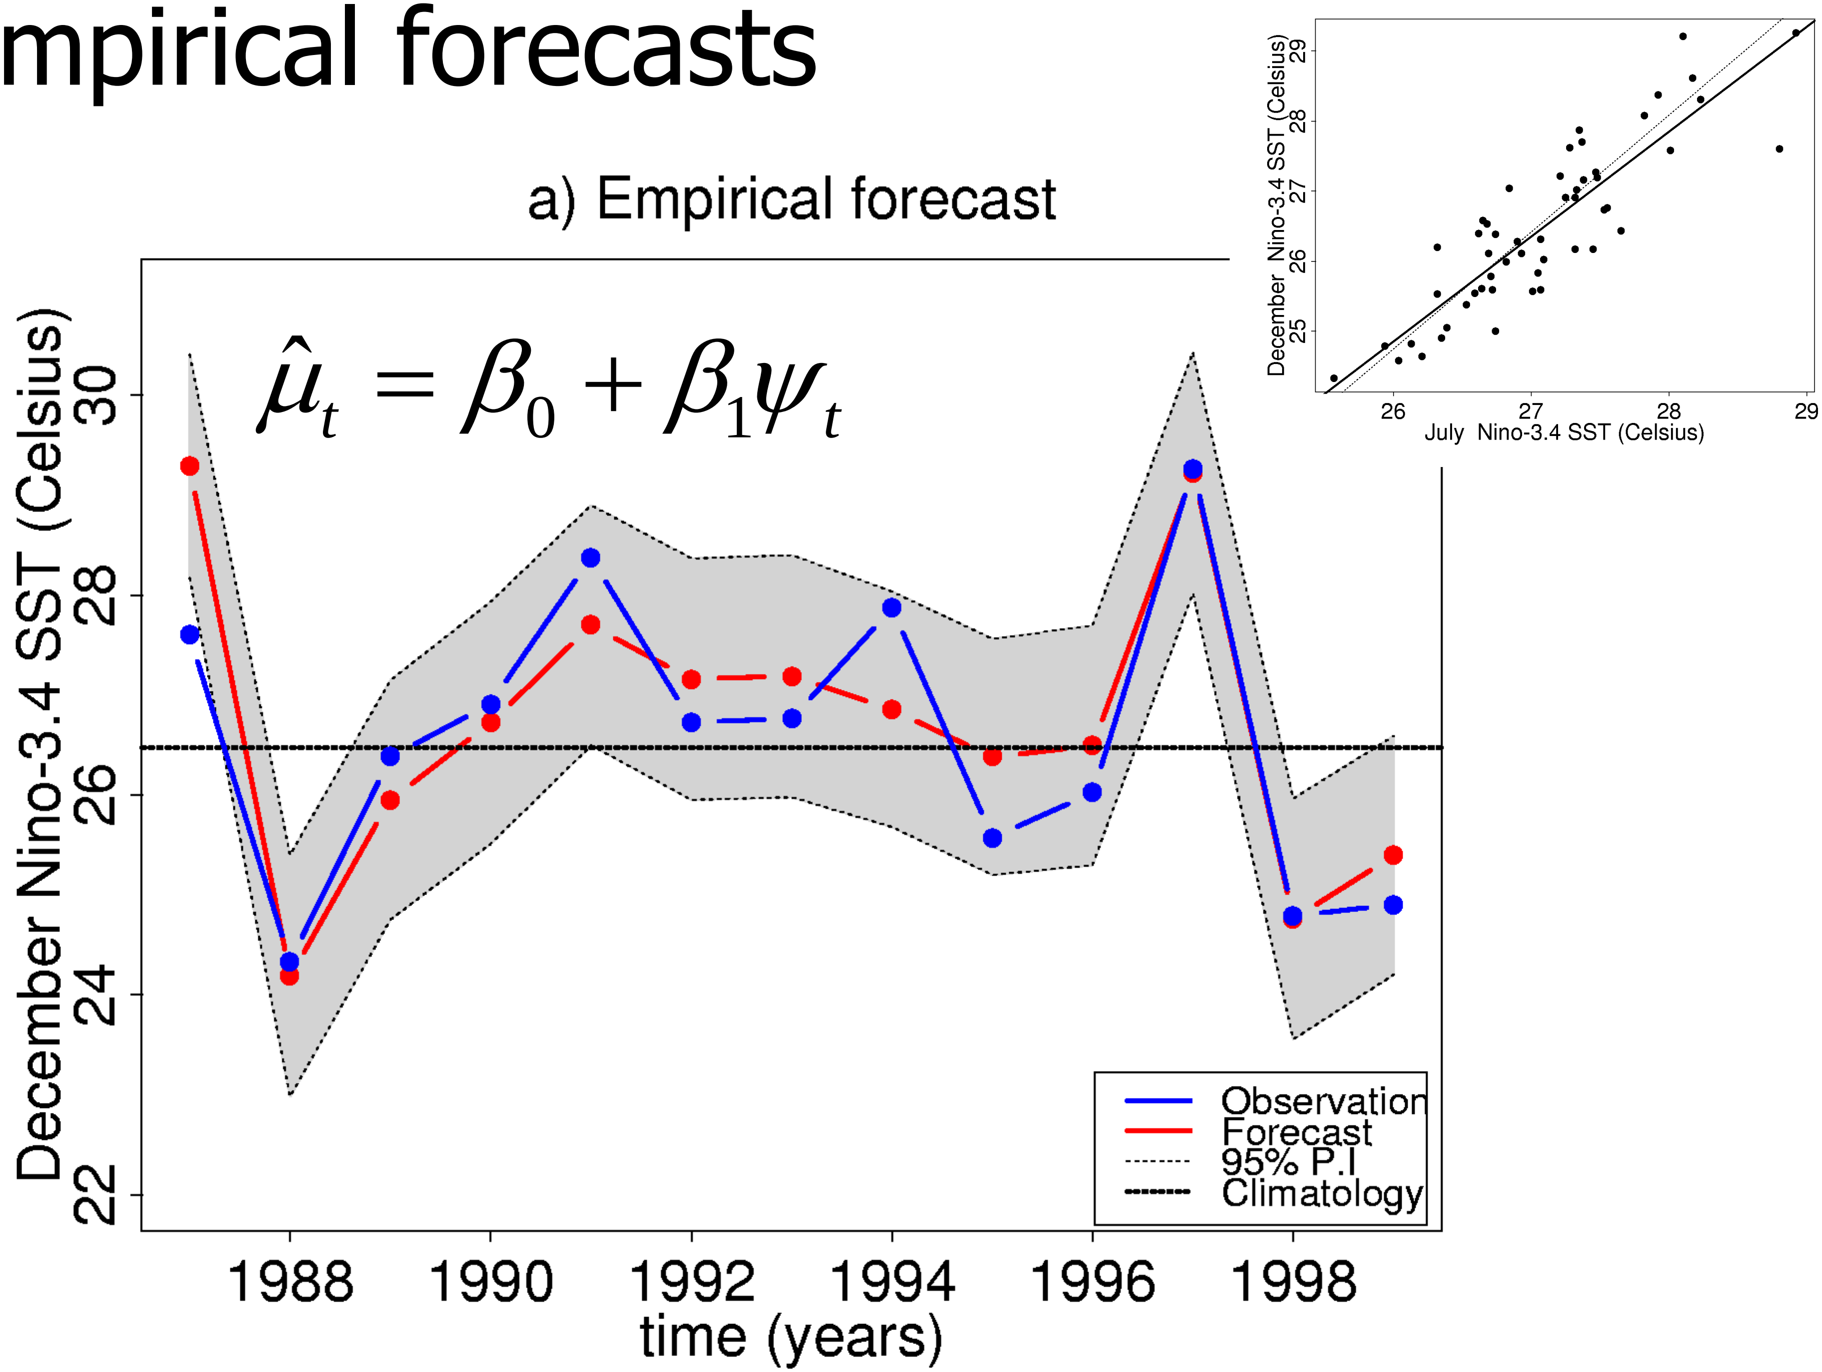
The Likelihood Model

$$\bar{X}_t \mid \theta_t \sim N(\alpha + \beta\theta_t, \gamma V_t)$$

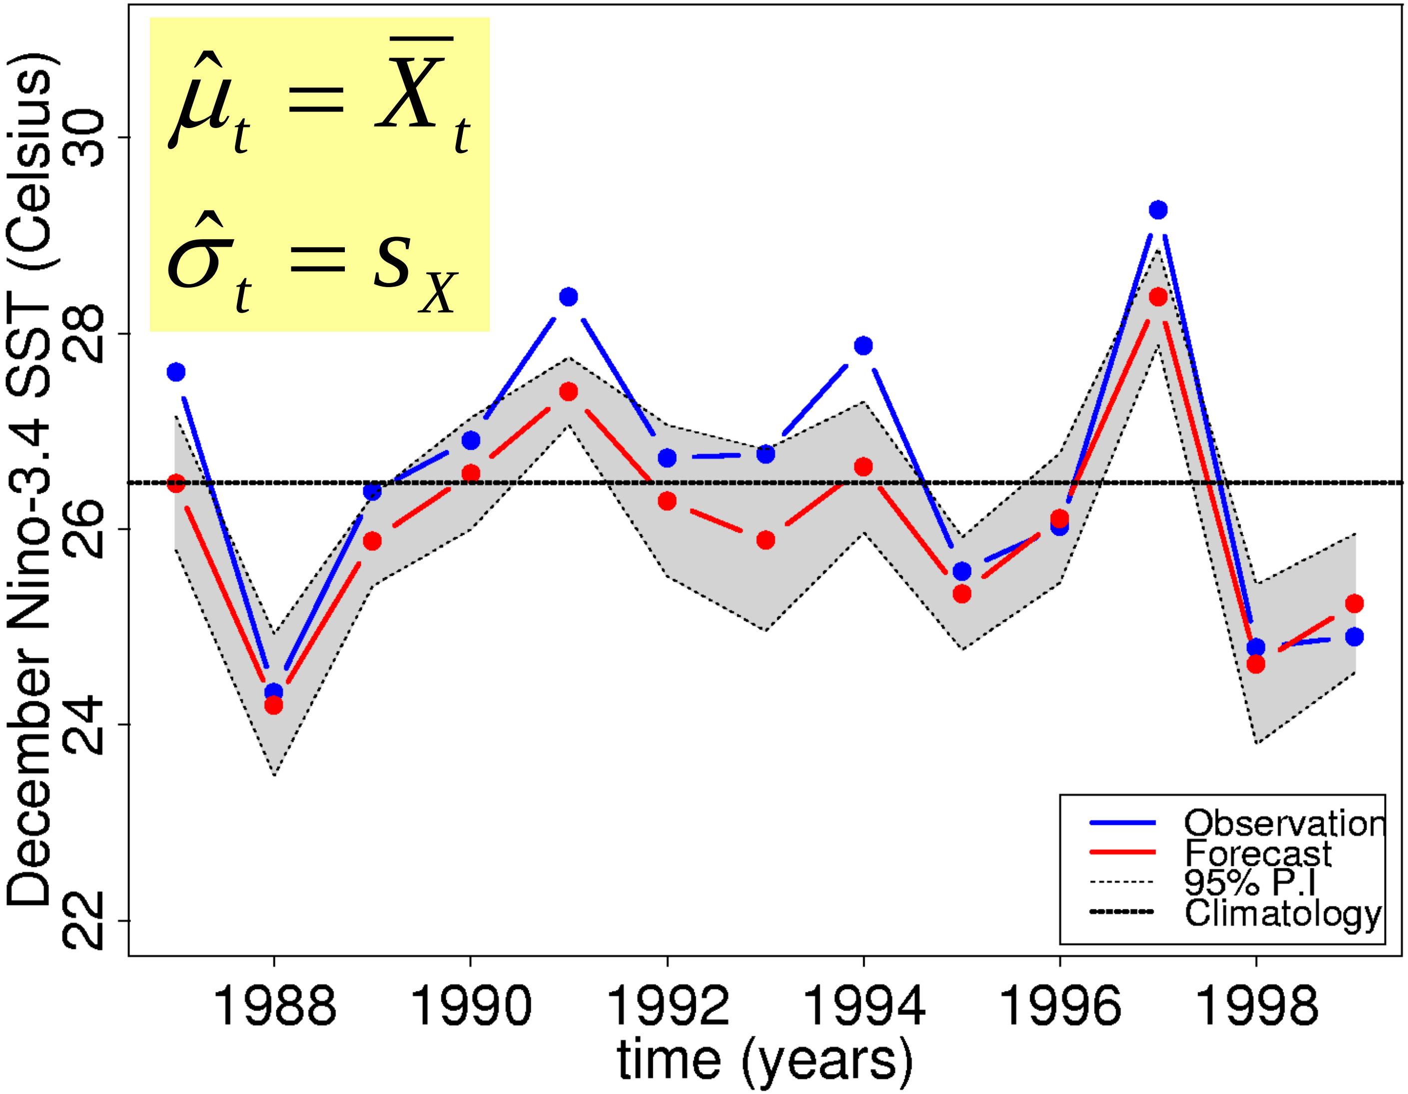


3. Forecast results

Empirical forecasts

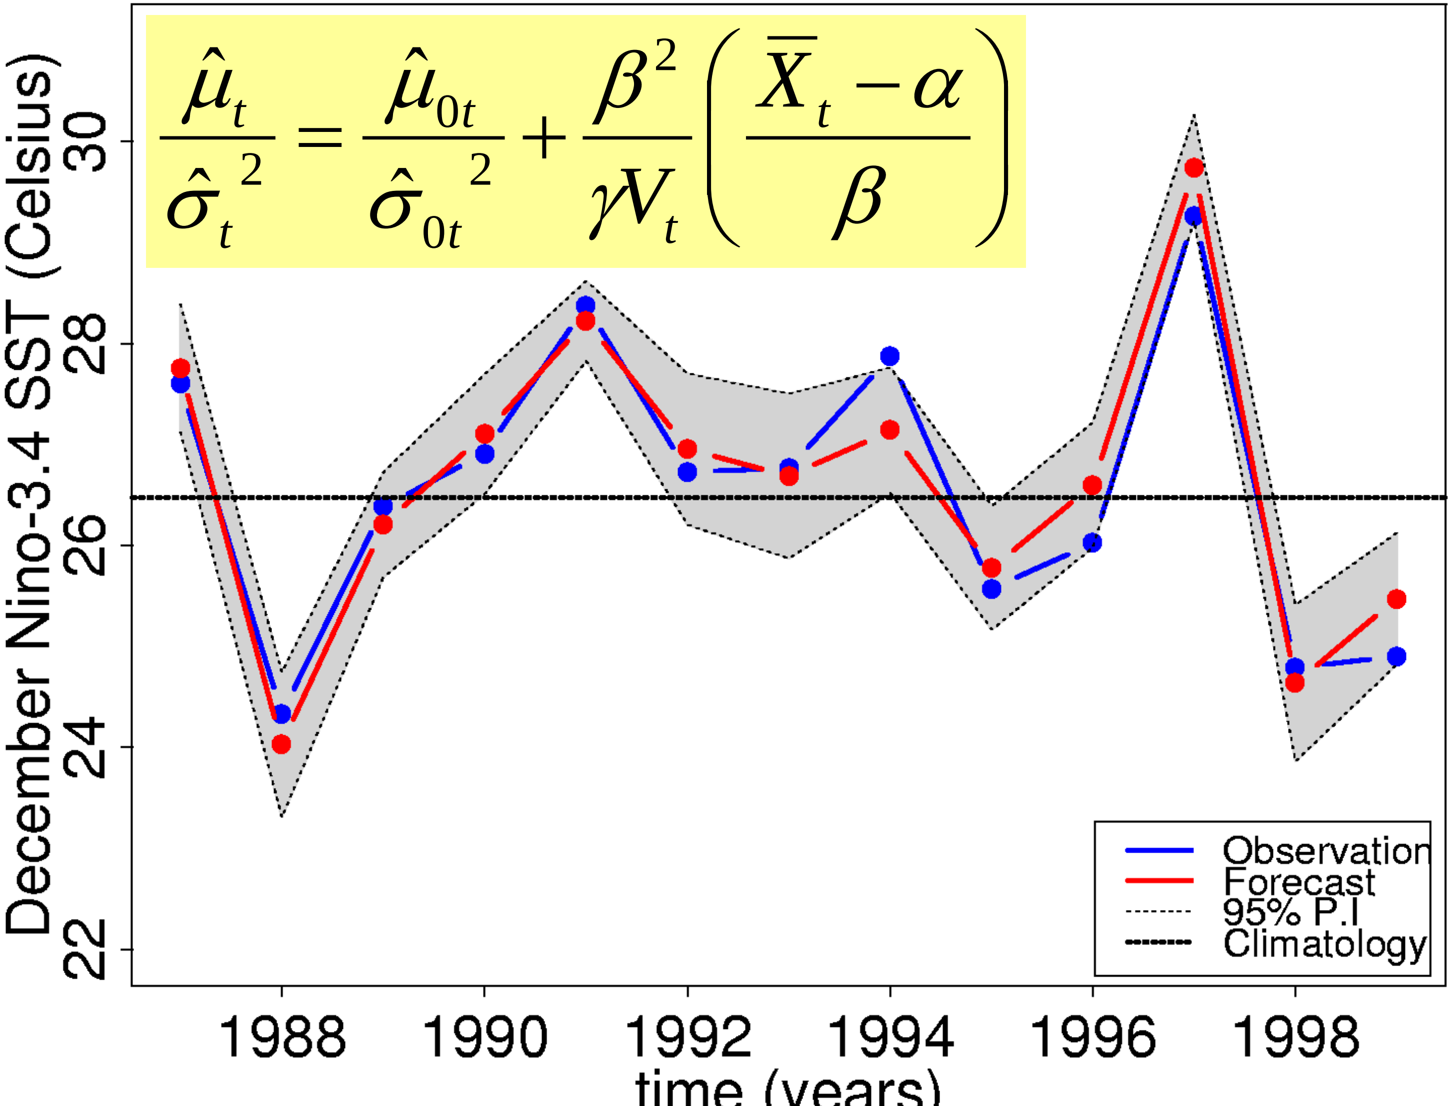


Coupled model forecasts



→ Note: many forecasts outside the 95% prediction interval!

Combined forecast



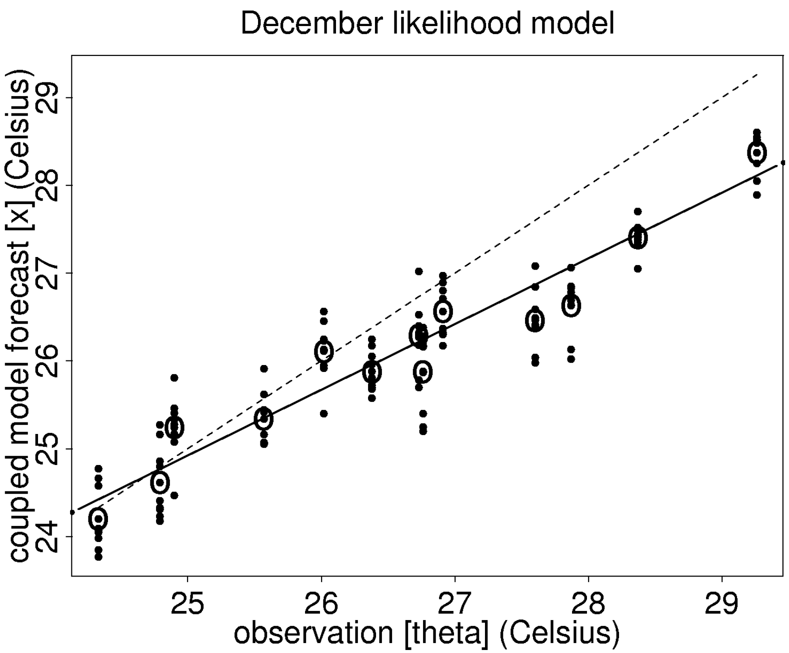
→ Note: more forecasts within the 95% prediction interval!

Mean likelihood model estimates

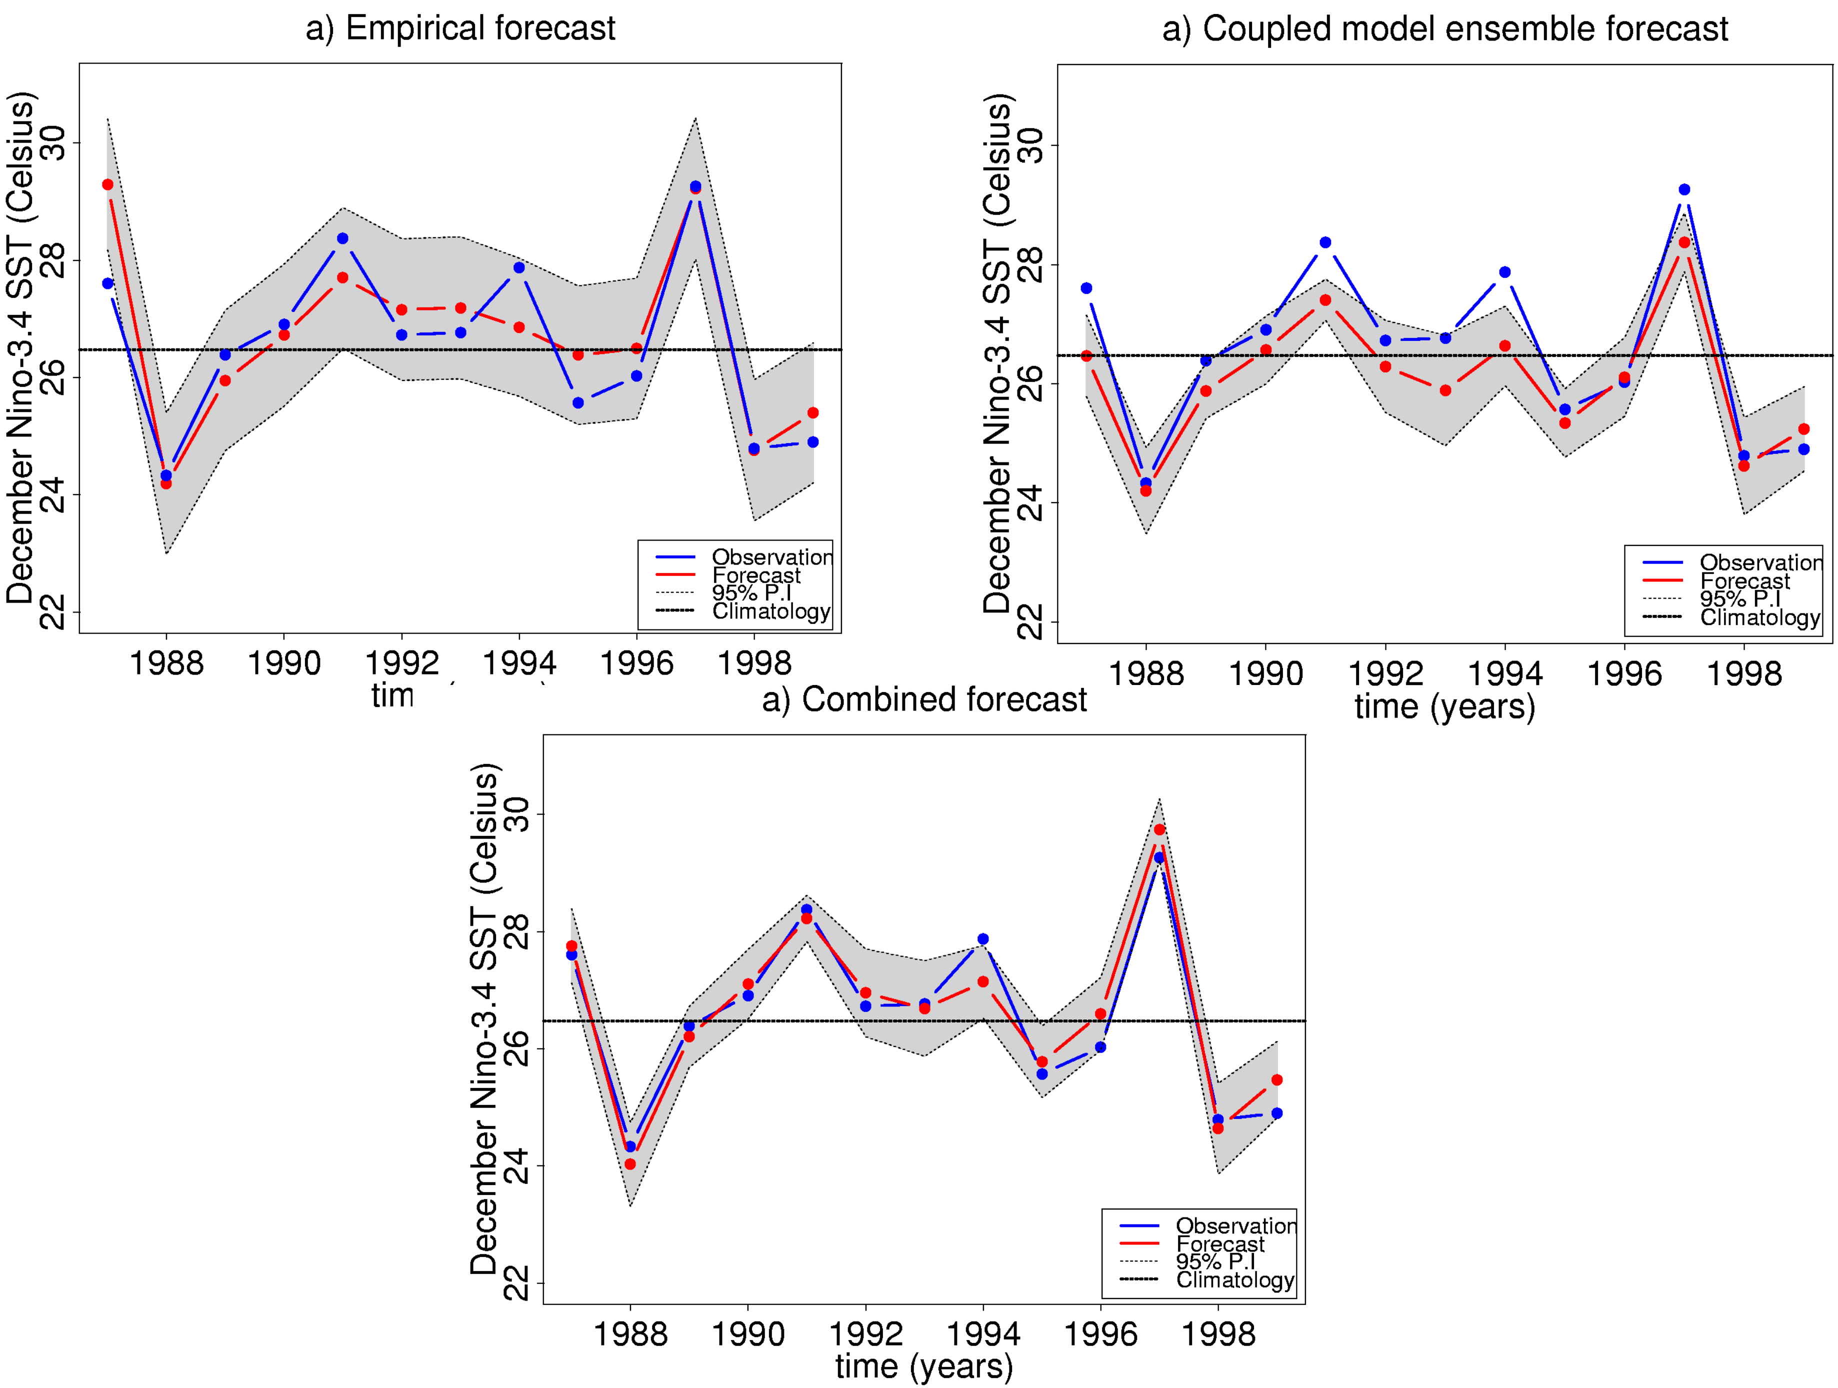
$$\hat{\alpha} = 6.27 \pm 1.44^{0}C$$

$$\hat{\beta} = 0.75 \pm 0.05$$

$$\hat{\gamma} = 7.05 = m / m'$$



- ensemble forecasts too cold on average (alpha>0)
- ensemble forecast anomalies too small (beta<1)
- ensemble forecast spread underestimates forecast uncertainty



a) Empirical forecast
a) Coupled model ensemble forecast
a) Combined forecast

Climatology

Forecast statistics and skill scores

Forecast	MAE (deg C)	Skill Score	Uncertainty
Climatology	1.16	0%	1.19 deg C
Empirical	0.53	55%	0.61
Ensemble	0.57	51%	0.33
Combined	0.31	74%	0.32
Uniform prior	0.37	68%	0.39

Note that the combined forecast has:
→A large increase in MAE (and MSE) forecast skill
→A realistic uncertainty estimate

Conclusions and future directions

- Bayesian combination can substantially improve the skill and uncertainty estimates of ENSO probability forecasts
- Methodology will now be extended to deal with multi-model DEMETER forecasts
- Similar approach could be developed to provide better probability forecasts at medium-range (Issues: non-normality, more forecasts, lagged priors, etc.).
