# Real Time System

- Real time systems have been defined as: “those systems in which the correctness of the system depends not only on the logical result of the computation, but also on the time at which the results are produced”
- Correct function at correct time
- Usually embedded
- Types
  - Hard real-time systems
  - Soft real-time systems

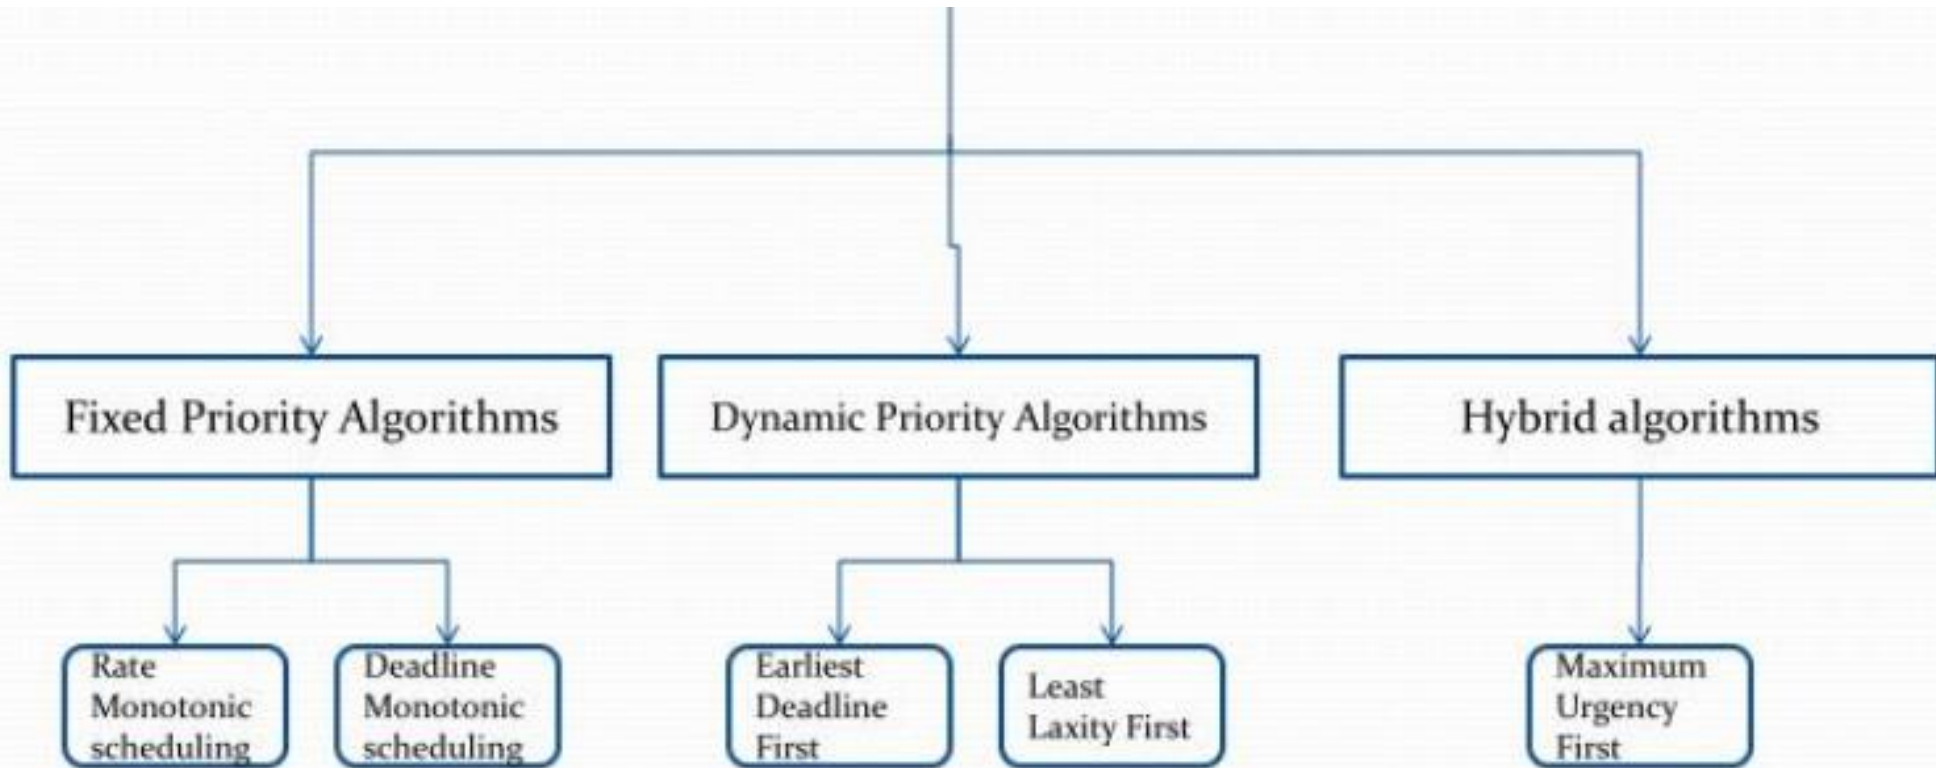

# Real Time System

- Soft real-time systems: meet timing constraints most of the time, it is not necessary that every time constraint be met. Some deadline miss is tolerated
- Hard real-time systems: meet all timeconstraints exactly, every resource management system must work in the correct order to meet time constraints. No deadline miss is allowed.

# Task categories

- Invocation
  - Periodic (time - triggered)
  - Aperiodic (event - triggered)
- Creation
  - Static
  - Dynamic
- Multi-Tasking system
  - Preemptive: higher priority process taking control of the processor from a lower priority
  - Non-Preemptive: each task can control the CPU for as long as it needs it

# Scheduling algorithms

# Rate monotonic scheduling

- Priority assignment based on rates of tasks
- Higher rate task assigned higher priority
- Schedulable utilization  $U_r$

$$U = \sum_{i=1}^n \frac{C_i}{T_i} \leq n(\sqrt[n]{2} - 1)$$

- if  $U > U_r$  schedulability is guaranteed
- Tasks may be schedulable even if  $U < U_r$

# Rate monotonic scheduling example

Process	Execution Time	Period
P <sub>1</sub>	1	8
P <sub>2</sub>	2	5
P <sub>3</sub>	2	10

The utilization will be:

$$\frac{1}{8} + \frac{2}{5} + \frac{2}{10} = 0.725$$

The theoretical limit for 3 processes, under which we can conclude that the system is schedulable is:

$$U = 3(2^{\frac{1}{3}} - 1) = 0.77976\dots$$

Since  $0.725 < 0.77976\dots$  the system is schedulable!

# Earliest deadline first

- Dynamic priority scheduling
- Priorities are assigned according to deadlines:
  - earlier deadline, higher priority
  - later deadline, lower priority
- The first and the most effectively widely used dynamic priority-driven scheduling algorithm
- Effective for both preemptive and non-preemptive scheduling

# Least Laxity First Cont

- LLF considers the execution time of task, which EDF does not
- LLF assigns higher priority to a task with the least laxity
- A task with zero laxity must be scheduled right away and executed without preemption or it will fail to meet its deadline
- The negative laxity indicates that the task will miss the deadline, no matter when it is picked up for execution

# Least Laxity First Example

	arrival	duration	deadline
T 1	0	10	33
T 2	4	3	28
T 3	5	10	29

$$l(T1) = 33 - 15 - 6 = 12$$

$$l(T3) = 29 - 15 - 2 = 12$$

$$l(T1) = 33 - 4 - 6 = 23 \quad l(T1) = 33 - 5 - 6 = 22 \quad l(T1) = 33 - 13 - 6 = 14 \quad l(T1) = 33 - 16 - 6 = 11$$

$$l(T2) = 28 - 4 - 3 = 21 \quad l(T2) = 28 - 5 - 2 = 21 \quad l(T2) = 28 - 13 - 2 = 13 \quad l(T3) = 29 - 16 - 1 = 12$$

$$l(T3) = 29 - 5 - 10 = 14 \quad l(T3) = 29 - 13 - 2 = 14$$
